

NAG Fortran Library Routine Document

F08ATF (CUNGQR/ZUNGQR)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

F08ATF (CUNGQR/ZUNGQR) generates all or part of the complex unitary matrix Q from a QR factorization computed by F08ASF (CGEQRF/ZGEQRF) or F08BSF (CGEQPF/ZGEQPF).

2 Specification

```
SUBROUTINE F08ATF(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
ENTRY      cungqr(M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER    M, N, K, LDA, LWORK, INFO
complex  A(LDA,*), TAU(*), WORK(*)
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3 Description

This routine is intended to be used after a call to F08ASF (CGEQRF/ZGEQRF) or F08BSF (CGEQPF/ZGEQPF), which perform a QR factorization of a complex matrix A . The unitary matrix Q is represented as a product of elementary reflectors.

This routine may be used to generate Q explicitly as a square matrix, or to form only its leading columns.

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. The whole of Q may be computed by:

```
CALL CUNGQR (M,M,P,A,LDA,TAU,WORK,LWORK,INFO)
```

(note that the array A must have at least m columns) or its leading p columns by:

```
CALL CUNGQR (M,P,P,A,LDA,TAU,WORK,LWORK,INFO)
```

The columns of Q returned by the last call form an orthonormal basis for the space spanned by the columns of A ; thus F08ASF (CGEQRF/ZGEQRF) followed by F08ATF (CUNGQR/ZUNGQR) can be used to orthogonalise the columns of A .

The information returned by the QR factorization routines also yields the QR factorization of the leading k columns of A , where $k < p$. The unitary matrix arising from this factorization can be computed by:

```
CALL CUNGQR (M,M,K,A,LDA,TAU,WORK,LWORK,INFO)
```

or its leading k columns by:

```
CALL CUNGQR (M,K,K,A,LDA,TAU,WORK,LWORK,INFO)
```

5 Parameters

1: M – INTEGER *Input*

On entry: m , the order of the unitary matrix Q .

Constraint: $M \geq 0$.

- 2: N – INTEGER *Input*
On entry: n , the number of columns of matrix Q that are required.
Constraint: $M \geq N \geq 0$.
- 3: K – INTEGER *Input*
On entry: k , the number of elementary reflectors whose product defines the matrix Q .
Constraint: $N \geq K \geq 0$.
- 4: A(LDA,*) – **complex** array *Input/Output*
Note: the second dimension of the array A must be at least $\max(1, N)$.
On entry: details of the vectors which define the elementary reflectors, as returned by F08ASF (CGEQRF/ZGEQRF) or F08BSF (CGEQPF/ZGEQPF).
On exit: the m by n matrix Q .
- 5: LDA – INTEGER *Input*
On entry: the first dimension of the array A as declared in the (sub)program from which F08ATF (CUNGQR/ZUNGQR) is called.
Constraint: $LDA \geq \max(1, M)$.
- 6: TAU(*) – **complex** array *Input*
Note: the dimension of the array TAU must be at least $\max(1, K)$.
On entry: further details of the elementary reflectors, as returned by F08ASF (CGEQRF/ZGEQRF) or F08BSF (CGEQPF/ZGEQPF).
- 7: WORK(*) – **complex** array *Workspace*
Note: the dimension of the array WORK must be at least $\max(1, LWORK)$.
On exit: if $INFO = 0$, the real part of $WORK(1)$ contains the minimum value of $LWORK$ required for optimum performance.
- 8: LWORK – INTEGER *Input*
On entry: the dimension of the array WORK as declared in the (sub)program from which F08ATF (CUNGQR/ZUNGQR) is called, unless $LWORK = -1$, in which case a workspace query is assumed and the routine only calculates the optimal dimension of WORK (using the formula given below).
Suggested value: for optimum performance $LWORK$ should be at least $N \times nb$, where nb is the **blocksize**.
Constraint: $LWORK \geq \max(1, N)$ or $LWORK = -1$.
- 9: INFO – INTEGER *Output*
On exit: $INFO = 0$ unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

$INFO < 0$

If $INFO = -i$, the i th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The computed matrix Q differs from an exactly unitary matrix by a matrix E such that

$$\|E\|_2 = O(\epsilon),$$

where ϵ is the *machine precision*.

8 Further Comments

The total number of real floating-point operations is approximately $16mnk - 8(m+n)k^2 + \frac{16}{3}k^3$; when $n = k$, the number is approximately $\frac{8}{3}n^2(3m - n)$.

The real analogue of this routine is F08AFF (SORGQR/DORGQR).

9 Example

To form the leading 4 columns of the unitary matrix Q from the QR factorization of the matrix A , where

$$A = \begin{pmatrix} 0.96 - 0.81i & -0.03 + 0.96i & -0.91 + 2.06i & -0.05 + 0.41i \\ -0.98 + 1.98i & -1.20 + 0.19i & -0.66 + 0.42i & -0.81 + 0.56i \\ 0.62 - 0.46i & 1.01 + 0.02i & 0.63 - 0.17i & -1.11 + 0.60i \\ -0.37 + 0.38i & 0.19 - 0.54i & -0.98 - 0.36i & 0.22 - 0.20i \\ 0.83 + 0.51i & 0.20 + 0.01i & -0.17 - 0.46i & 1.47 + 1.59i \\ 1.08 - 0.28i & 0.20 - 0.12i & -0.07 + 1.23i & 0.26 + 0.26i \end{pmatrix}.$$

The columns of Q form an orthonormal basis for the space spanned by the columns of A .

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
