M01CCF – NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1   Purpose

M01CCF rearranges a vector of character data so that a specified substring is in ASCII or reverse ASCII order.

2   Specification

```
SUBROUTINE M01CCF(CH, M1, M2, L1, L2, ORDER, IFAIL)
INTEGER        M1, M2, L1, L2, IFAIL
CHARACTER*1    ORDER
CHARACTER*(*)  CH(M2)
```

3   Description

M01CCF is based on Singleton's implementation of the 'median-of-three' Quicksort algorithm [2], but with two additional modifications. First, small subfiles are sorted by an insertion sort on a separate final pass (Sedgewick [1]). Second, if a subfile is partitioned into two very unbalanced subfiles, the larger of them is flagged for special treatment: before it is partitioned, its end-points are swapped with two random points within it; this makes the worst case behaviour extremely unlikely.

Only the substring (L1:L2) of each element of the array CH is used to determine the sorted order, but the entire elements are rearranged into sorted order.

4   References

[1]   Sedgewick R (1978) Implementing quicksort programs *Comm. ACM* **21** 847–857

5   Parameters

1:   CH(M2) — CHARACTER*(*)   *Input/Output*

On entry: elements M1 to M2 of CH must contain character data to be sorted.

Constraint: the length of each element of CH must not exceed 255.

On exit: these values are rearranged into sorted order.

2:   M1 — INTEGER   *Input*

On entry: the index of the first element of CH to be sorted.

Constraint: M1 > 0.

3:   M2 — INTEGER   *Input*

On entry: the index of the last element of CH to be sorted.

Constraint: M2 ≥ M1.

4:	L1 — INTEGER	*Input*
5:	L2 — INTEGER	*Input*

On entry: only the substring (L1:L2) of each element of CH is to be used in determining the sorted order.

Constraint: $0 < L1 \leq L2 \leq LEN(CH(1))$.

6: ORDER — CHARACTER*1 *Input*

On entry: if ORDER is 'A', the values will be sorted into ASCII order; if ORDER is 'R', into reverse ASCII order.

Constraint: ORDER = 'A' or 'R'.

7: IFAIL — INTEGER *Input/Output*

On entry: IFAIL must be set to 0, −1 or 1. For users not familiar with this parameter (described in Chapter P01) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

If on entry IFAIL = 0 or −1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors detected by the routine:

IFAIL = 1

On entry, M2 < 1,
or M1 < 1,
or M1 > M2,
or L2 < 1,
or L1 < 1,
or L1 > L2,
or L2 > LEN(CH(1)).

IFAIL = 2

On entry, ORDER is not 'A' or 'R'.

IFAIL = 3

On entry, the length of each element of CH exceeds 255.

7 Accuracy

Not applicable.

8 Further Comments

The average time taken by the routine is approximately proportional to $n \times \log n$, where $n = M2 - M1 + 1$. The worst case time is proportional to n^2, but this is extremely unlikely to occur.

The routine relies on the Fortran 77 intrinsic functions LLT and LGT to order characters according to the ASCII collating sequence.

9 Example

The example program reads a file of 12-character records, and sorts them into reverse ASCII order on characters 7 to 12.

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
